Calculate the value of appropriate test

In Statistical analysis, the value is Z-value

Z-test → Z-value    ANOVA → F-value  
t-test → t-value    chi-square → chi-square

2 Probability distribution of test statistic

gives you the probability of occurrence  
of each value of the test

$P_{value}$  = 几率 تحقيق قيمة

وهي تقرئ احتمال حدوث هذه القيمة  
وأكبر من قيم المعيار

critical value → area Chance  تكون تحقيق values

كذلك في تحقيق من المعنى المرتبط بالقيم

وتحقيق في التجربة

② for  $\alpha$

٥% d

$$Z = \pm 2.58$$

③ for  $\alpha/2 = 0.01 = 2.58$

2.58

$$Z = \pm 3.27$$

one-tail

Two-tailed

$$\alpha_{0.05} Z = 1.65$$

$$\alpha = 0.5 Z = \pm 1.96$$

$$\alpha = 0.1 Z = 2.32$$

$$\alpha = 0.01 Z = \pm 2.57$$

$$\alpha = 0.001 Z = 3.08$$

$$\alpha = 0.001 Z = \pm 3.27$$

null hypothesis:  $H_0$

$H_1, H_2$  vs.  $H_0$  افتر

there is no significant difference

Hint:-

We can't prove that  $H_0$  is true. We can only obtain evidence to reject the null hypothesis

alternative hypothesis

$H_1 < H_2$   $H_1 > H_2$

$H_1 \neq H_2$

there is difference

مقدمة

Sunday

25

٢٠٢٣ جمعه ١٧

الآخر Sunday

What does it mean to reject the null hyp?

- our sample means fall   outside the critical region
- the Z-score of our sample mean is   less than greater than the Z-critical value
- the probability of obtaining the sample mean   is less than ~~greater than~~ the alpha level

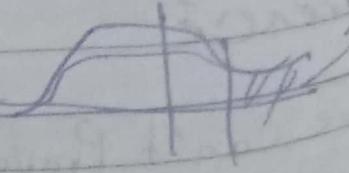

Significant difference: means the sample

statistic we test is very different than what we would expect for all other samples

we could have gotten from the population

$$(\bar{Z} = \frac{\bar{X} - \mu}{\sigma/\sqrt{n}})$$

reject the null  $\Rightarrow$  lie in the critical region

Problems

For understand Udacity Problem 8

Numerous studies have demonstrate that listening to music while studying can improve memory.

To demonstrate this phenomenon a researcher obtains a sample of 36 college student and give them a standardized memory test while they listen to background music. Under normal circumstances without any music, the scores on the test form a normal distribution with  $\mu = 25$  and  $SD = 6$ . The sample mean

$\bar{x} = 22$ . Use a  $t$ -test for a one-tailed t-test.

Wednesday  
21Z-test works when we know  $\sigma$  and  $n$ Samples

How different a sample mean is from a population.

2. How different two sample means are from each other \*dependent  
\*independent

$$\text{Sample Mean} = \sqrt{\frac{\sum (x_i - \bar{x})^2}{n-1}}$$

When  $n$  increases the

① t-distribution approaches a normal distribution

② the t-distribution gets skinnier tails

3

## Types of effect size Measures

### ① Difference Measures

→ Mean difference → SD differences  
Like Cohen's d =  $\frac{\text{mean difference}}{\text{SD}}$  → standardized difference  
Cohen's d =  $\frac{\text{mean difference}}{\text{SD}}$  = SD units

### ② Correlation Measures

$r^2$  - Proportion (%) of variation in one variable that is related to another variable

### Statistical significance

Means:-

① rejected the null hypothesis.

also ② results are not likely due to chance

when you see word "statistical significant"

All it means is that the results are probably not due to chance

\* When P-value is  $< 5\%$  or lower is often considered to be statistically significant

\* Statistical significance is a determination about the null hypothesis

which suggests that the results are due to chance alone.

A data set provides statistical significance when the P-value is sufficiently small

\* When P-value is large, then the results in the data are explainable by chance alone. And the data are deemed consistent with null hypothesis (Accept null)

\* When the P-value is small (typically  $< 5\%$  or less) the results are not easily explained by chance only

and the data are deemed inconsistent with the null hypothesis. So the null hypothesis is rejected

প্রতিকূল পদ্ধতি সম্ভব নয়। এটা সহজেই বর্ণনা করা যায়।

সুবিধা ও উপর গোপনীয় পদ্ধতি।

\* alternative hypothesis tells us what we're hoping to find

\* the standard error tells us that we expect sample mean to differ from the true population mean by  $\pm 1\sigma$ , on average

explain Meaning Of t & P-value

assume  $t = -1.711$

$P \leq 0.05$

the P-value is the area less

than  $-1.711$

it's just a proportion scores

falls beyond a critical

so  $P < 0.05$

December 2022

Monday

١٢

Advantages of dependent samples  
→ Repeated Measures

+ Two conditions + longitudinal \* Pre & Post - test

- ① it controls individual differences
- ② use fewer subjects ③ cost-effective
- ④ less time-consuming
- ⑤ less expensive

### disadvantages

- \* carry-over effects
- \* the second measurement can be affected by first treatment
- \* order may influence results

## Independent samples

Using experimental test }  
or observational }

Very-imp note

$$M_1 - N(M_2, \sigma^2) = N(\bar{M}_1 - \bar{M}_2, \sqrt{\sigma_1^2 + \sigma_2^2})$$

مذكر

How to know which sample is different from other samples?

We use ~~one~~ a new test called:-

**«Multiple comparison test»**

one of them is called: "Tukey's HSD"

Honestly significant difference

is the difference between two means which is significant at level  $\alpha$ .  
Like,  $\bar{x}_3 - \bar{x}_1$ ,  $\bar{x}_1 - \bar{x}_2$  etc.

Margin of error =  $Z^* \cdot \frac{\sigma}{\sqrt{n}}$

or  $= t^* \cdot \frac{s}{\sqrt{n}}$

with Tukey's HSD we have  $q^*$

$$\leq q^* \cdot \sqrt{\frac{MS_{\text{within}}}{n}} = q^* \cdot s_p$$

Studentized Range statistic

3	4	5	6	7	8	9
10	11	12	13	14	15	16
17	18	19	20	21	22	23
24	25	26	27	28	29	30

٤	٥	٦	٧	٨	٩	١٠
١٧	١٨	١٩	٢٠	٢١	٢٢	٢٣
٢٤	٢٥	٢٦	٢٧	٢٨	٢٩	٣٠
٢١	٢٢	٢٣	٢٤	٢٥	٢٦	٢٧

the HSD value which we calculate from eqn.

$$\text{Tukey's HSD} = q^* \sqrt{\frac{MS_{\text{within}}}{n}}$$

Means that if any two samples have an absolute difference greater than

2.51, this difference is considered honestly significant

so if  $|\bar{x}_i - \bar{x}_j| > \text{HSD value}$

this test made only if all sample size is the same

Owen's d for knowing the effect of sample size

$$\frac{\bar{x}_i - \bar{x}_j}{\text{MS}_{\text{within}}}$$

$$\sqrt{\frac{MS_{\text{between}}}{MS_{\text{within}}}}$$

another effect size measure for one way ANOVA is called eta square  $\eta^2$

$\eta^2$  similar to  $r^2$  in t-test

\* this effect size tells us the proportion of total variation that is due to between group differences

$$\eta^2 = \frac{SS_{\text{between}}}{SS_{\text{between}} + SS_{\text{within}}}$$

## Reporting results of ANOVA

$$F(2,6) = 27 \quad P < 0.05 ; \eta^2 = 9.0\%$$

## ANOVA assumptions

- ① normally distributed
- ② homogeneity of variance
- ③ Independence of observations

(Measurement scale)

tutorial topics:-

① What Measurement scale is?

② Four types of Measurements scales

nominal - ordinal - Interval - Ratio

Definition

- \* Measurement involves the assignment of a value
- \* Measurement scales define the nature of values

some scales is word Measurement  
like gender {Male - Female}

others use numbers

Properties of Measurement scales:

① Identity: each value on the Measurement has unique Meaning

② Magnitude: Values has an ordered relationship to one another

③ Equal interval

↳ Scale units along the scale are equal to one another

↑  
Some are smaller and some are larger

For ex:-

Wednesday  
30

		1	2	3	4
5	8	7	9	10	11
12	13	14	15	16	17
19	20	21	22	23	24
26	27	28	29	30	31

١	٢	٣	٤
١١	١٢	١٣	١٤
١٥	١٦	١٧	١٨
١٩	٢٠	٢١	٢٢
٢٣	٢٤	٢٥	٢٦
